## High spatial resolution study of the Nearest Active Galactic Nuclei

Compilation of the highest spatial resolution data available

- Angular scales of  $\theta < 0.1''$
- UV + OP + IR + radio

What is new are the achieved angular scales in the 1 to 20 $\mu\text{m}$  from 8 – 10 class telescopes

- 1 - 5  $\mu\text{m}$   $\rightarrow \theta < 0.1''$
- 10 - 20  $\mu\text{m}$   $\rightarrow \theta < 0.5''$
- Interferometry at 10  $\mu\text{m}$   $\rightarrow \theta < 0.05''$

What we have:

- HST at 0.3 - 0.9  $\mu\text{m}$   $\rightarrow \theta < 0.1''$

What we partially have:

- VLA/ VLBA  $\rightarrow \theta < 0.1''$

# On the nearest AGN

- AGN cores in the IR have sizes less than a few tens of pc
- Their SEDs are characterised by a conspicuous bump peaking in the 2-10  $\mu\text{m}$  range. This bump is very steep at the shortest wavelengths in type 2, but shallower in type 1.
- Their IR luminosities are above 80% of the total, this being taken as  $L_{\text{total}} = L_{\text{IR}} + L_{X_{20-100 \text{ keV}}}$
- Their IR luminosities can be up to several orders of magnitude lower than that of their host galaxy
- Yet, AGN with luminosities above  $10^{44}$  erg/s are as quasars, dominating in full the total IR light of the galaxy
